What Cybersecurity Is

Video 1 · What Security Is, and Why It Matters

Security Fundamentals · Section 1

In this video, you will learn:

- How one email can lock an entire business
- What cybersecurity is, in plain words
- Why it matters now, for a business, a person, and a country

How one email locks a business

*A common attack called **ransomware**:*

- *An employee gets an email: "Your bill is overdue, open the attached invoice."*
- *They open the attachment. It quietly encrypts the company's files and waits.*
- *One morning: "Your files are locked. Pay to get them back." Sales records, staff details, supplier list, all unreadable.*

***No lock was picked. No window was broken. One email, one click.** Something valuable, a way in, a weakness, and harm: that is the whole subject in one picture.*

What cybersecurity is

Cybersecurity is protecting information and the systems that hold it from people who should not read it, change it, or stop it from working.

- ***Information:*** *records, a phone number, a password, a bank balance.*
- ***Systems:*** *laptops, phones, servers, apps, websites, and the networks between them.*
- ***People who should not:*** *from a curious insider to a criminal who locks files for money.*

It is not one product you buy. It is an ongoing practice: understand what could go wrong, protect what matters, and watch for what gets through.

Why it matters now

Almost everything runs on computers and networks, and an attack can reach it from anywhere in the world.

What depends on computers	What an attack can do
A business's records and payroll	Lock the files; stop the business
A person's phone	Read private chats; steal from a banking app
A bank or payment app	Move money; take over accounts
A hospital's records	Block access during an emergency

In Cambodia, as online banking and QR payments spread, scams and account takeovers grow with them. Security is for every business and every phone, not only big companies.

Risk, not perfection

No system is ever perfectly safe, and trying to make one perfect costs more than it is worth.

Security asks four questions about anything that could go wrong:

- *What could happen?*
- *How likely is it?*
- *How bad would it be?*
- *What does it cost to prevent?*

A coffee shop needs less protection than a bank. ***Neither needs zero.***

Recap: what security is

- *One email and one click can lock a whole business: that is the harm security prevents.*
- *Cybersecurity protects **information and systems** from people who should not read, change, or stop them.*
- *Everything runs on computers now, so the harm can reach anyone, anywhere.*
- *Security is about **risk**, not perfection.*

***Next video:** what we protect, and what threatens it.*

What Cybersecurity Is

Video 2 · What We Protect, and What Threatens It

Security Fundamentals · Section 1

In this video, you will learn:

- *What an "asset" is, and why reputation counts as one*
- *The three questions at the heart of all security*
- *The difference between a threat, a vulnerability, and a risk*

Assets: what is worth protecting

An **asset** is anything that has value to you, and so might have value to an attacker. You defend what matters most, first.

Asset (a dental clinic)	Why it has value
Patient records	Private and legally protected
The appointment system	Down = no patients seen
Payment and banking details	Direct access to money
The clinic's reputation	Patients who feel unsafe leave

Trust and reputation are assets too. You can restore files from a backup in an hour; winning back a patient's trust takes much longer.

The three questions

*Look at any system and ask three things. The next lesson studies them as the **CIA triad**.*

1. ***Can the wrong people _read_ it?** → confidentiality (only you and your bank read your balance)*
2. ***Can the wrong people _change_ it?** → integrity (nobody changes an order from $100 to $1)*
3. ***Can the wrong people _stop_ it?** → availability (hospital records open in an emergency)*

*Ransomware is a **stop** attack: the files are not read or changed, just made unusable when they are needed.*

Threat, vulnerability, risk

Three words people mix up. They are different things.

- ***Threat:*** *a bad thing that could happen. "A criminal could lock our files for money."*
- ***Vulnerability:*** *a weakness that lets it happen. "Staff open attachments without checking."*
- ***Risk:*** *the chance of the two meeting, and how bad it would be.*

> ***Risk = how likely × how bad.***

*A threat with no matching weakness is little risk. Security work is finding the risks that are both **likely** and **serious**, and reducing them first.*

Recap: what we protect

- ***Assets** are what is worth protecting, including trust and reputation.*
- *The three questions: can the wrong people **read**, **change**, or **stop** it?*
- *A **threat** is the bad event, a **vulnerability** is the weakness, a **risk** is the chance and cost of the two meeting.*

***Next video:** how we defend, and the one rule you must never break.*

What Cybersecurity Is

Video 3 · How We Defend, and the One Rule

Security Fundamentals · Section 1

In this video, you will learn:

- Why defense is built in layers
- Why security is everyone's job
- Why we learn to attack, and the one rule that keeps it legal

Defense in depth

The ransomware did not have to win. Five ordinary layers:

1. ***Training:*** *staff pause at a strange invoice email.*
2. ***An email filter:*** *the message goes to junk.*
3. ***Up-to-date software:*** *the attachment's trick no longer works.*
4. ***A separate daily account:*** *the locking program cannot reach every file.*
5. ***A nightly backup, kept disconnected:*** *files restored in an hour.*

The attacker must beat ***all five****. Miss the filter? Training stops the click. Click anyway? The backup saves the day.*

Every layer can fail, so we never rely on one.

Security is everyone's job

The weak point in a ransomware attack is rarely a machine. It is an ordinary email and an ordinary click.

Who	Their part
The owner / manager	Decides what matters; pays for backups and training
The staff	Spot strange emails; use good passwords
The developer	Builds software that does not leak or over-trust
The server / IT	Checks every request; owns the decisions
The specialist	Finds weaknesses; watches and responds

The danger: each part assuming another has it covered. "We have antivirus, so we don't need backups."

Why we learn to attack

This program teaches real attacks, in a safe lab. Why, if the goal is to defend?

Because you cannot defend against what you do not understand.

If you have never seen how a file is locked or a password is cracked, your defenses are guesses.

- *A **locksmith** must understand lock-picking to fit good locks.*
- *The skill is the same; **permission and intent** decide right from wrong.*
- *Hired to pick your lock: a professional. The same act on a stranger's door: a burglar.*

The one rule

> ***Only ever test systems that you own, or that you have clear, written permission to test.***

Every tool here is powerful. On your own lab, it is a skill that pays well. On someone else's system without permission, the same action is a crime.

- *"I was only curious" is **not** permission.*
- *"It was easy to break into" is **not** permission.*
- *"I only looked, I didn't change anything" is **not** permission.*

Your own lab, or written permission. There is no third option.

The road ahead

This is one of 43 courses. Everyone starts with Foundations, then picks a path.

Stage	What you gain
Foundations	The ground every security person stands on
Offensive	How attacks really work, hands-on in the lab
Defensive	How to watch, catch, and recover from attacks
Engineering	How to build systems that resist attack
Specialized	Deep fields, and turning the skills into a job

After Foundations and one path, you are employable. A full professional eventually touches all of them.

Recap: how we defend

- ***Defense in depth:*** *several layers, so one failure is not a disaster.*
- *Security is* ***everyone's job****; the weakest point is often a person and a click.*
- *We* ***learn to attack*** *so we can defend; permission and intent make it right.*
- ***The one rule:*** *only test what you own, or have written permission to test.*

Next lesson: *The CIA triad and beyond, the three questions studied in depth.*
